

# Your question bank

Name \_\_\_\_\_

Three questions your own data can answer, one sentence each. Then swap with a neighbour, who writes box 4. Pin the sheet on the wall.

**1. To check it.** A question you already know the answer to.

**2. To explore.** A question you do not know the answer to.

**3. To catch it.** A question your data cannot answer.

**4. Question 1, 20 percent more specific.** Written by your neighbour: which column, which unit, which comparison.

At 10:06 you type the three questions into `questions.md` in your repository and commit them by hand. Question 1 runs the framed run at 10:39. Question 2 is card 1, question 3 is card 2. Sprint 2 is a choice: question 1 done properly, or question 2.
